

TITLE OF THE INVENTION

Navigation Device and Navigation Method

CROSS-REFERENCE TO THE RELATED APPLICATION

5 This Application is a continuation of International Application No. PCT/JP99/06344, whose International filing date is November 12, 1999, the disclosures of which Application are incorporated by reference herein, and which International Application was not published in English.

10 BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a navigation device and a navigation method, which display a route from a present position of a vehicle to a destination and guide the vehicle to the destination.

15

2. Description of the Related Art

A navigation device is provided with a display screen which is opened as required by a driver or is opened automatically when guiding a route or the device may be provided with a display screen which is used when setting 20 a route.

In particular, JP-A-9-133541 discloses a technique by which intersections at which the vehicle turns to the left or the right (hereafter turning points) on a guided route are detected and a plurality of such turning point intersection names are displayed on a display screen.

25 Furthermore, JP-A-6-68386 discloses a technique by which when a vehicle is travelling on a route, a subsequent intersection through which the vehicle will pass is detected and a name of the intersection is displayed on a display screen.

Since the conventional navigation device is constructed as above, the

problem has arisen that although the name of intersection through which the vehicle will subsequently pass is displayed on a display screen, even if a user recognizes the name of a subsequent intersection, it is not possible to determine how many intersections ahead the turning point intersection is 5 located and thus it is not possible to easily understand the route.

SUMMARY OF THE INVENTION

The present invention is proposed to solve the above problems and has the object of providing a navigation device and a navigation method 10 which can clearly display turning point intersections and thus facilitate the route recognition.

A navigation device of the present invention is adapted to display the name of intersections extracted by a route guiding means and the distance to the intersections while displaying a route searched by a route searching 15 means.

In such a way, route recognition is facilitated and it is possible to take precautions to prevent divergence from the route.

The navigation device of the present invention may be adapted to confirm passage of the intersection by the vehicle and to give a change 20 command with respect to the intersection to be displayed to the display means.

In such a way, it is possible to ensure recognition of only the forward turning point intersections from the present position.

The navigation device of the present invention may be adapted to 25 display a direction of travel at an intersection when the intersection extracted from the route guiding means is a turning point intersection.

In such a way, immediate recognition is enabled of at which forward intersection turning should be performed from the present position and thus the direction of travel can be varied at ease.

The navigation device of the present invention may be adapted to display an intersection with emphasis when the intersection extracted by the route guiding means is a turning point intersection.

In such a way, immediate recognition is enabled of at which forward 5 intersection turning should be performed from the present position and thus the direction of travel can be varied at ease.

The navigation device of the present invention may be adapted to display a fact of a non-recordal of an intersection name when the name of the intersection extracted by the route guiding means is not recorded on a map 10 information.

In such a way, it is possible to prevent missing a small intersection the name of which is not recorded.

The navigation device of the present invention may be adapted to generate a temporary name of an intersection from information linked to the 15 intersection and to display the temporary name, when the name of the intersection extracted by the route guiding means is not recorded on a map information.

In such a way, it is possible to prevent missing a small intersection the name of which is not recorded.

20 The navigation device of the present invention may be adapted to display a landmark or a traffic signal mark together with the name of an intersection when information relating to the landmark or the traffic signal mark which is related to the intersection extracted by the route guiding means is recorded on a map information.

25 In such a way, it is possible to facilitate intersection discrimination.

The navigation device of the present invention may be adapted to display intersections at points of traffic congestion with emphasis when traffic congestion information with respect to the route searched by the route searching means is received.

In such a way, it is possible to recognize traffic congestion on a scheduled route.

A navigation method of the present invention is adapted to display the name of each of intersections existing on a route from a present point of a vehicle to a destination and the distance to each of the intersections, while displaying the route.

In such a way, route recognition is facilitated and it is possible to take precautions to prevent divergence from the route.

The navigation method of the present invention may be adapted to
10 change an intersection to be displayed upon the confirmation of the vehicle passing through the intersection.

In such a way, it is possible to ensure recognition of only intersections which exist on the route forward of the present position.

The navigation method of the present invention may be adapted to
15 display a direction of travel at an intersection when the intersection existing on the route is a turning point intersection.

In such a way, immediate recognition is enabled of at which forward intersection turning should be performed from the present position and thus the direction of travel can be changed with ease.

20 The navigation method of the present invention may be adapted to display an intersection with emphasis when the intersection existing on the route is a turning point intersection.

In such a way, immediate recognition is enabled of at which forward intersection turning should be performed from the present position and thus
25 the direction of travel can be changed with ease.

The navigation method of the present invention may be adapted to display a fact of a non-recordal of an intersection name when the name of the intersection existing on the route is not recorded on a map information.

In such a way, it is possible to prevent missing a small intersection

the name of which is not recorded.

The navigation method of the present invention may be adapted to generate a temporary name of an intersection from information related to the intersection and to display that temporary name, when the name of the 5 intersection existing on the route is not recorded on a map information.

In such a way, it is possible to prevent missing a small intersection the name of which is not recorded.

The navigation method of the present invention may be adapted to display a landmark or a traffic signal mark together with the name of an 10 intersection when information relating to the landmark or the traffic signal mark which is related to the intersection existing on the route is recorded on a map information.

In such a way, it is possible to facilitate intersection discrimination.

The navigation method of the present invention may be adapted to 15 display intersections at points of congestion with emphasis when traffic congestion information with respect to the searched route is received.

In such a way, it is possible to recognize traffic congestion on a scheduled route.

20 BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 shows a navigation device according to a first embodiment of the present invention.

Fig. 2 is a block diagram showing the structure of hardware of the navigation device as shown in Fig. 1.

25 Fig. 3 is a flowchart of a navigation method according to the first embodiment of the present invention.

Fig. 4 describes the display contents of a screen.

Fig. 5 describes the display contents of a screen.

Fig. 6 describes the display contents of a screen.

Fig. 7 describes an intersection name list.

Fig. 8 describes the display contents of a screen.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

5 In order to describe the invention in greater detail, the preferred embodiments of the present invention will be described below with reference to the accompanying figures.

Embodiment 1

10 Fig. 1 shows a navigation device according to a first embodiment of the present invention. In the figures, reference numeral 1 denotes a control means which executes each type of calculation and which performs control of other constituting elements in the navigation device.

15 2 is an operation means by which a user inputs the destination and the like of a vehicle. 3 is a present position detection means which detects a present position of the vehicle, 4 is a map information recording means for recording digitized map information data such as link data and node data showing intersections, roads and the like. 5 is a route searching means which searches a route between the two geographic points, from a present 20 position to a destination, referring to the map information data recorded in the map information recording means 4. 6 is a route recording means which records the route determined by the route searching means 5.

25 7 is a route guiding means which extracts intersections existing on the route searched by the route searching means 5, specifies turning point intersections and the like and calculates the distance from the present position of a vehicle to each intersection. The route guiding means 7 performs determination of intersections to be passed and intersections at which turning is performed from road categories and the connecting angles of adjacent links. Furthermore, the route guiding means 7 decides the

timing of changing information with respect to the intersections passed and effects read-out operation of the intersection information from the map information recording means 4.

8 is a display means which displays a route recorded on the route recording means 6 and which displays the name of each intersection extracted by the route guiding means 7, the distance to each intersection and the like. 9 is a voice guiding information extraction means which extracts main guiding information from guiding information related to the route recorded in the route recording means 6.

10 10 is a voice control means which converts voice data to analog signals and generates a voice guiding message, when a guiding command is received from the control means 1. 11 is a voice output means which outputs a voice signal corresponding to the voice guiding message generated by the voice control means 10 and which informs a user of the guiding message.

Fig. 2 is a block diagram showing the structure of hardware of the navigation device as shown in Fig. 1. In the figures, reference numeral 21 denotes a reading device, which is provided with a compact disk read-only memory (CD-ROM) in which digitized map information data is stored. The 20 reading device 21 corresponds to the map information recording means 4 in Fig. 1.

22 is a GPS receiver which receives radio waves from an artificial satellite using a global positioning system (GPS) and detects a present position of the vehicle. 23 is a bearing sensor which detects a bearing in which the vehicle is traveling. 24 is a distance sensor which detects the traveled distance of the vehicle.

The present position detection means as shown in Fig. 1 is comprised of the GPS receiver 22, the bearing sensor 23 and the distance sensor 24.

25 is a display device which has for example a liquid crystal display

and which displays a determined route and the like as well as a map and map information on the basis of the map information data. The display device 25 corresponds to the display means 8 in Fig. 1.

26 is a voice output device which outputs a voice guiding message

5 and which corresponds to the voice output means 11 in Fig. 1.

27 is an input device which has a switch which is operated when a command is input to the navigation device by a user and which supplies the user command to the control unit 28. The input device 27 corresponds to the operation means 2 in Fig. 1.

10 28 is a control unit which is comprised of a central processing unit (CPU) 31, a read-only memory (ROM) 32, a random access memory (RAM) 33, a display control section 34 and an input/output control section 35. The control unit 28 executes each type of calculation in the navigation device and performs control of other constituting elements. The control unit 28 corresponds to the control means 1, the route searching means 5, the route recording means 6, the route guiding means 7, the voice guiding information extraction means 9 and the voice control means 10 in Fig. 1.

31 is a CPU which executes processing such as route searching and guiding point extraction, 32 is a ROM which pre-stores programs and data 20 which are used in the CPU 31. 33 is a RAM, to which the program and data used in the CPU 31 are loaded, and which stores calculation results due to the CPU 31. 34 is a display control section which controls the display device 25 and displays each type of image on the display device 25. 35 is an input/output control section which acts as an interface between the control 25 unit 28 and each external device (read-out device 21 - input device 27) and which performs transfer of signals and each type of data.

Fig. 3 is a flowchart of a navigation method according to the first embodiment of the present invention.

The operation of the navigation device according to the present

invention will be described below.

Firstly, when a destination is input from the operation means 2 by a user, under control of the control means 1 the route searching means 5 refers to the map information data stored in the map information recording means 4 and searches a route between the two geographic points from a present position detected by the present position detection means 3 to a destination for example by use of a Dijkstra method or the like. Thus, a single route is determined as the route of the vehicle (for example, shortest route).

The route for the vehicle, which is the search result of the route searching means 5, is stored in the route recording means 6. Under control of the control unit 1, the route guiding means 7 refers to map information data recorded in the map information recording means 4 and extracts intersections (nodes) existing on the route of the vehicle in sequence from those in proximity to the present position.

The route guiding means 7, as shown in Fig. 7, extracts node numbers indicative of the intersections and the intersection names from the map information data and stores such information in an intersection name list (step ST1).

The intersection names are extracted from additional information with respect to the nodes, which is recorded in the map information data. On the other hand, when the intersection names are not added as the additional information with respect to the nodes, the term "no name" is stored in the intersection name list.

Subsequently, the route guiding means 7 refers to the map information data and calculates distances to five forward intersections from the present position (five intersections existing on the route which are proximate to the present position).

After the calculation of the distances from the present position to the five forward intersections by the route guiding means 7, the display means 8

displays, under control of the control means 1, a route stored in the route recording means 6 on the map, which is displayed on the left side of the screen, as shown in Fig. 4. The names of the five forward intersections and the distance to each intersection are displayed on the right side of the screen
5 (step ST2). However, when the intersection names are not stored in the intersection name list, either the term "no name" is displayed or the name column is left blank and only the distance is displayed.

When the name of intersections or the like are displayed on the right side of the screen, the display means 8 emphasizes display of turning point
10 intersections by displaying intersections recognized as the turning point intersections by the route guiding means 7 in a different color to that of other intersections (hereafter termed transit intersections). The direction of travel in the turning point intersections is displayed by an arrow (step ST3, ST4).

15 In the example shown in Fig. 4, an intersection "Shimagaya" which is the fifth intersection from the present position is recognized as a turning point intersection and displayed with emphasis. It is noted that in the example shown in Fig. 4, the first intersection "Shiyakushomae" from the present position is also displayed with emphasis.

20 In such a way, names and distances from a present position to five forward intersections are displayed, and further, turning point intersections and an immediately subsequent intersection are displayed with emphasis. Therefore, a user can perceive the vehicle route.

Next, when the transit of the first intersection from the present
25 position detected by the present position detection means 3 is recognized by the route guiding means 7 (step ST5), the display means as shown in Fig. 5 deletes information with respect to the transit intersection passed by the vehicle and adds information with respect to a new intersection (step ST6, ST7).

In other words, when the vehicle passes through the intersection of "Shiyakushomae" and an intersection "Akasaka" becomes the next intersection, intersection information (name and distance) with respect to the intersection "Shiyakushomae" is deleted, intersection information with
5 respect to intersections from the intersection "Akasaka" to the intersection "Shimagaya" are respectively scrolled downwards, and intersection information with respect to an intersection "Nagao" which becomes the new fifth intersection is displayed on the uppermost position.

However, in the step ST6, if a transit intersection passed by the
10 vehicle is determined to be the last intersection on the route, a series of operations is completed.

As described above, according to the first embodiment, the navigation device is adapted to display a route from a present position of a vehicle to a destination and to display a distance to each intersection and the
15 name of each intersection located on the route. Thus, it is possible to sensuously understand the direction of travel at an intersection, and as a result, to take precautions to prevent divergence from the route.

Turning point intersections may be displayed with emphasis from among the intersections displayed on a map located on the left side of the
20 screen. However, when the intersection information is not displayed on the right side of the screen, it is not possible to sensuously understand at which intersection turning is to be performed or the distance to the turning point intersection. Thus, even when the turning point intersections are displayed with emphasis on a map located on the left side of the screen, it is necessary
25 to display the intersection information on the right side of the screen.

Embodiment 2

In the first embodiment, after passing through an intersection, information relating to the transit (passed) intersection is deleted and

information relating to a new intersection is added to the display. However, as shown in Fig. 6, the amount of displayed intersection information may be successively reduced by not adding new intersection information until a turning point intersection is passed.

5 In this case, it is possible to sensuously perceive approach to the turning point intersection with greater ease.

Further, in the first embodiment above, the navigation device is adapted to successively display all transit intersections. However, only information relative to intersections which cross roads having a fixed road 10 category may be displayed.

Furthermore, in the first embodiment above, a map and the present position are displayed on the left side of a screen in the display device 25 and a plurality of intersection information is displayed on the right side of the screen. However, the intersection information may be displayed on the left 15 side of the screen or on a lower or upper section of the screen.

In the first embodiment above, turning point intersections are displayed in a different color to the transit intersections. However, the color of the turning point intersections may be varied in accordance with the distance to the turning point intersection.

20 In the first embodiment above, a route for the vehicle is displayed on the left side of the screen. However, when the vehicle approaches an intersection, the display may be switched to a deformation map which shows the details of the intersection.

25 Embodiment 3

In the first embodiment above, when the intersection name is not added to the node additional information, the display "no name" is displayed. However, the navigation device may be adapted to generate a temporary name for the intersection from information related to the intersection and

display the temporary name.

That is to say, a temporary name for the intersection may be generated from road width of intersecting roads or proximate place names and the temporary name may be displayed.

5 For example, if a width of an intersecting road is less than 3m, "intersection with road of less than 3m" may be displayed. If an address of an intersection is "Sanda-shi Miwa 2-chome", "intersection near Sanda-shi Miwa 2-chome" may be displayed.

10 In this way, it is possible to prevent missing a small intersection the name of which is not recorded.

Further, in the first embodiment above, a name of an intersection is displayed. However, the navigation device may be adapted to display an entrance number of an expressway, a road name (street name), a road number of the intersecting road or the like.

15 It is noted that while traveling on an expressway, no intersections exist on the route traveled. Thus, interchanges, parking areas, service areas may be regarded as intersections and these names and the distance thereto may be displayed.

20 Embodiment 4

In the first embodiment above, the intersection name, the distance to the intersection and the direction of travel are displayed as intersection information. However, as shown in Fig. 8, when information about a traffic signal or a landmark related to the intersection existing on the route is recorded as map information data, the traffic signal mark or the landmark (for example, hospital or gasoline station) may be displayed next to the information relating to the intersection.

25 In such a way, it is possible to further facilitate the discrimination of the intersection.

Embodiment 5

In the first to fourth embodiments above, the reception of VICS information is not particularly noted. However, when the navigation device is adapted to receive the VICS information transmitted from a signpost of the intersection or the like, traffic congestion information on the route may be extracted from the VICS information. If congestion positions exist, such positions are displayed as blinking displays on the map and intersections at points of the congestion are displayed with emphasis.

For example, when the traffic congestion is generated between the intersection "Shiyakushomae" and the intersection "Akasaka", the names of the intersection "Akasaka" and the intersection "Shiyakushomae" are displayed as blinking displays and a traffic congestion mark is displayed. Thus, intersections at points of the traffic congestion are clarified.

In such a way, it is possible for a user to recognize the traffic congestion on a scheduled route.

As shown above, a navigation device and a navigation method according to the present invention are adapted to indicate a route from a present position of a vehicle to a destination, and when the vehicle is guided to the destination, it is possible to take precautions to prevent divergence from the route by appropriately presenting the intersection information.
